QuickBooks: Reimagining Accounting With System One Models

(1st place: $200 gift card per person, 2nd place: $100 gift card per person, 3rd place: $50 gift card per person)

QuickBooks serves businesses of all sizes, from solopreneurs and small businesses to growing mid-market companies. Across these customers, many of the most important jobs are fundamentally financial: understanding the health of the business, getting paid and paying others on time, managing cash flow, staying profitable, preparing for taxes, and making confident decisions about hiring, spending, and growth.

System One models, such as Jev, introduce a new set of capabilities and performance characteristics that may enable experiences that were previously impractical or impossible. They create an opportunity to rethink how intelligent systems can help businesses interact with their financial data, make decisions, and get work done.

For this hackathon, we want to explore where these models can create meaningful new value for QuickBooks users. The most interesting ideas may improve existing workflows, but we especially encourage teams to look for entirely new experiences that classical machine learning or conventional generative AI could not reasonably enable.

Anything is in scope, with a few principles guiding judging:

- The System One approach should create a meaningful technical unlock.
- The solution should demonstrate something that was not previously possible (or was prohibitively slow, expensive, or difficult) with classical ML or conventional GenAI. Significant improvements in latency, cost, or scale can qualify if they fundamentally change the user experience or the ability of a company to provide it. For example, dramatically faster inference might make real-time, interactive financial analysis possible where it was previously too slow or expensive. The strongest projects will likely unlock a genuinely new class of experience.
- The unlock should translate into clear customer value.
- Technical novelty alone is not enough. The solution should solve a meaningful problem for QuickBooks users and make an important task easier, faster, better, automated, or newly possible.
- Teams should demonstrate the advantage with realistic evaluation.

Hackers are expected to define their own evaluation methodology and show evidence that their approach performs meaningfully better than relevant alternatives, such as classical ML systems or LLM-based approaches. Evaluations should reflect realistic usage and quality standards rather than toy examples. Designing and running these evaluations will likely be a significant part of the hackathon work.

A submission does not strictly need to use a System One model. However, it should embody the System One spirit: taking advantage of capabilities such as speed, efficiency, specialization, or new model

architectures to enable experiences that conventional approaches cannot. For example, SemIf, Ollaya, and similar approaches are completely within scope. Where possible, solutions should be designed around a System-One-compatible API.

Provided Data

Synthetic accounting data for multiple companies across different industries are provided. Hackers are free to modify or extend the data to create the business scenarios needed to develop, test, benchmark, and demonstrate their work. Any modifications should be clearly disclosed, including what was changed and why.
